Specimen Type

MCR

Peripheral blood

Final Diagnosis

[1] MCR

Peripheral blood, JAK2 V617F mutation analysis:

Positive. JAK2 V617F mutated DNA was detected and measured at 44% of total JAK2 DNA.

JAK2V617F mutation is found with high frequency in Philadelphia chromosome-negative myeloproliferative neoplasms (>95% in polycythemia vera and approximately 50–60% in primary myelofibrosis and essential thrombocythemia). It can also occur in other myeloid neoplasms, such as refractory anemia with ring sideroblasts associated with marked thrombocytosis (RARS-T) and rarely in myelodysplastic syndrome, chronic myelomonocytic leukemia, atypical chronic myeloid leukemia and acute myeloid leukemia. Clinicopathologic correlation is recommended for a definitive diagnosis.

The precision of JAK2 mutation percentage measurement is such that values 2 times higher or lower than the reported value are considered equivalent.

No further testing for JAK2 mutation was performed as it is not indicated per PVJAK test algorithm. See test catalogue for additional information.

Method summary - JAK2 V617F analysis: Quantitative, allele-specific polymerase chain reaction (PCR) assay was performed using extracted genomic DNA to evaluate for the point mutation causing JAK2 V617F. The analytic sensitivity of this assay has been determined at 0.06% (see Mayo Clinic Laboratories Interpretive Handbook for method details).
