MAYO CLINIC LABORATORIES

Test Definition: MCSTP

MayoComplete Solid Tumor Panel,
Next-Generation Sequencing, Tumor

Overview

Useful For

Assisting in tumor profiling for diagnosis, predicting prognosis, and identifying targeted therapies for the treatment and management of patients with solid tumors

Identifying somatic alterations including single nucleotide variants, small deletions/insertions, gene amplifications, homozygous gene deletions, fusions, and splice variants in genes known to be associated with the tumorigenesis of solid tumors

Assessment of microsatellite instability and tumor mutational burden status

Genetics Test Information

This test uses targeted next-generation sequencing to estimate tumor mutational burden and detect microsatellite instability, sequence variants, gene amplifications, homozygous gene deletions, fusions, and specific transcript variants in solid tumors. This panel includes a DNA subpanel for the detection of sequence alterations in 515 genes, amplification of 96 genes, homozygous deletion of 133 genes, as well as an RNA subpanel for the detection of fusions involving 55 genes and specific splice variants involving *EGFR*, *AR*, and *MET*. Sequence variants and copy number changes are concomitantly interpreted to evaluate for complete inactivation of 31 tumor suppressor genes. See Genes Interrogated by MayoComplete Solid Tumor Panel for details regarding genes interrogated by this test.

This test is performed to evaluate for somatic (ie, tumor-specific) alterations within the genes listed. Although germline (ie, inherited) alterations may be detected, this test cannot distinguish between germline and somatic alterations with absolute certainty. Follow-up germline testing using whole blood can be performed for confirmation of suspected clinically relevant germline alterations. Germline testing should be performed along with genetic counselling.

Additional Tests

Test Id	Reporting Name	Available Separately	Always Performed
SLIRV	Slide Review in MG	No, (Bill Only)	Yes

Testing Algorithm

When this test is ordered, slide review will always be performed at an additional charge to ensure specimen adequacy.

Special Instructions

- Genes Interrogated by MayoComplete Solid Tumor Panel
- MayoComplete Solid Tumor Panel DNA Panel Excluded DNA Regions

Method Name

Sequence Capture and Targeted Next-Generation Sequencing (NGS)

NY State Available
Yes

Specimen

Specimen Type
Varies

Ordering Guidance
Multiple oncology (cancer) gene panels are available. For more information see Hematology, Oncology, and Hereditary Test Selection Guide.

Necessary Information
A pathology report (final or preliminary), at minimum containing the following information, **must accompany specimen for testing to be performed**:
1. Patient name
2. Block number-must be on all blocks, slides, and paperwork (can be handwritten on the paperwork)
3. Tissue collection date
4. Source of the tissue
5. Pathologic diagnosis (final or preliminary)

Specimen Required
This assay requires at least 20% tumor nuclei. However, 40% tumor is preferred.
-Preferred amount of tumor area: 432 mm(2) tissue on up to 20 unstained slides
-Minimum amount of tumor area: 72 mm(2) tissue on up to 20 unstained slides
-Tissue fixation: 10% neutral buffered formalin, not decalcified
-For this test, at least 4.6 mm x 4.6 mm areas on 20 unstained slides is preferred: this is approximately equivalent to 432 mm(2). The minimum acceptable area is 1.9 mm x 1.9 mm on 20 unstained slides: approximately equivalent to 72 mm(2).

Preferred: Submit 3, if available, or 2 of the following specimens.
Acceptable: Submit **at least one** of the following specimens**.**

Specimen Type: Tissue block
Collection Instructions: Submit a formalin-fixed, paraffin-embedded tissue block with acceptable amount of tumor tissue.

Specimen Type: Tissue slide
Slides: 1 Hematoxylin and eosin-stained and 20 unstained
Collection Instructions:

Submit the followings slides:
1 Slide stained with hematoxylin and eosin
AND
20 Unstained, nonbaked slides with 5-micron thick sections of the tumor tissue.
Note: The total amount of required tumor nuclei can be obtained by scraping up to 20 slides from the same block.
Additional Information: Hematoxylin and eosin-stained and unstained slides will not be returned.

Specimen Type: Cytology slide (Diff-Quik, Pap-stained direct smears, or ThinPrep)
Slides: 2 to 6 Slides
Collection Instructions: Submit at least 2 slides, stained and coverslipped, with a total of 10,000 nucleated cells (preferred) or at least 2000 nucleated cells (minimum) per slide.
Note: Glass coverslips are preferred; plastic coverslips are acceptable but will result in longer turnaround times.
Additional Information: Cytology slides will not be returned. An image of the slides will be stored per regulatory requirements.

Forms
If not ordering electronically, complete, print, and send a Oncology Test Request (T729) with the specimen.

Specimen Minimum Volume
See Specimen Required

Reject Due To
All specimens will be evaluated at Mayo Clinic Laboratories for test suitability.

Specimen Stability Information

Specimen Type	Temperature	Time	Special Container
Varies	Ambient (preferred)		
	Refrigerated		

Clinical & Interpretive

Clinical Information
Targeted cancer therapies are defined as antibody or small molecule drugs that block the growth and spread of cancer by interfering with specific cell molecules involved in tumor growth and progression. Multiple targeted therapies have been approved by the US Food and Drug Administration for the treatment of solid tumor malignancies. Molecular genetic profiling is often needed to identify targets amenable to targeted therapies and to minimize treatment costs and therapy-associated risks. Tumor mutational burden and microsatellite instability status are increasingly important biomarkers for determining effective immunotherapeutic treatment options for patients with solid tumors.(1,2)

In addition to providing therapeutic insight, molecular profiling of tumors often provides prognostic and diagnostic information. Next-generation sequencing is an accurate, cost-effective method to identify variants across numerous genes known to be associated with response or resistance to specific targeted therapies. This test is a single assay that uses formalin-fixed paraffin-embedded tissue or cytology specimens to assess for Tier I and Tier II variants in 515 genes

known to be associated with solid tumors.(3)

Reference Values
An interpretive report will be provided.

Interpretation
The interpretation of molecular biomarker analysis includes an overview of the results and the associated diagnostic, prognostic, and therapeutic implications.

Cautions
Test results should be interpreted in the context of clinical, tumor sampling, histopathological, and other laboratory data. If results obtained do not match other clinical or laboratory findings, contact the laboratory for discussion. Misinterpretation of results may occur if the information provided is inaccurate or incomplete.

Reliable results are dependent on adequate specimen collection and processing. This test has been validated on cytology slides and formalin-fixed, paraffin-embedded tissues; other types of fixatives are discouraged. Treatment of tissues, such as decalcification, may cause polymerase chain reaction failure.

To ensure accuracy, this test will be performed on cases that are estimated by a pathologist to have 20% or more tumor cells, however, for optimal performance of this assay, a tumor purity of 40% is recommended.

This test does not differentiate between somatic and germline alterations. Additional testing may be necessary to clarify the significance of results if there is a potential hereditary risk.

This test does not detect large structural variants, large copy number changes, or deletions-insertions greater than approximately 20 base pairs in size.

Rare variants (ie, polymorphisms) may be present that could lead to false-negative or false-positive results.

A negative (ie, wildtype) result does not rule out the presence of an alteration that may be present but below the limits of detection of this assay.

The presence or absence of a variant or rearrangement may not be predictive of response to therapy in all patients.

A list of genomic regions in the DNA panel that have insufficient coverage to reliably detect single nucleotide variants and small deletions/insertions are listed in MayoComplete Solid Tumor Panel DNA Panel Excluded DNA Regions.

Supportive Data
Performance Characteristics

Verification studies demonstrated concordance between this test and the reference method for detection of single nucleotide variants (SNV) and deletions-insertions (delins) in 98.8% (503/509) and 98.6% (294/298) of variants, respectively. Detection accuracy of delins was 99.3% (277/279) in variants 1 to 10 base pairs (bp) in size, 93.3% (14/15) in variants 11 to 20 bp in size, and 75.0% (3/4) in variants greater than 20 bp in size.

The limit of detection for calling a somatic variant (SNV and small delins) is 2% variant allele frequency (VAF) for regions having at least 150X median exon coverage depth. Gene amplification and homozygous gene deletion detection are most accurate at 40% or more tumor purity. For gene amplifications, the overall sensitivity was 100% (79/79), specificity was 100% (11,249/11,249), and accuracy was 100% (11,328/11,328). For homozygous gene deletion the overall sensitivity was 95.1% (116/122), specificity was 99.99% (15,570/15,572), and accuracy was 99.9% (15,686/15,696). For bi-allelic inactivation, the overall sensitivity was 100% (140/140), specificity was 100% (3,518/3,518), and accuracy was 100% (3,658/3,658).

Of the 130 microsatellite sites available for evaluation in this assay, at least 20% of sites are required to be unstable to classify the case as MSI-High. Microsatellite instability (MSI) evaluation is most accurate at a tumor purity of 40% or more, although, highly unstable tumors may be detectable at 20% tumor. During verification studies, 100% concordance was observed between this test and orthogonal methods used to detect MSI status.

Tumor mutational burden (TMB) was measured as mutations per megabase (Mb) for regions with greater than 50X coverage. When TMB scores were classified as TMB-Low (<10 mut/Mb) or TMB-High (> or =10 mut/Mb), 83.3% (50/60) concordance was achieved between this test and orthogonal assays detecting TMB status. TMB values are most accurate at greater than or equal to 40% tumor purity.

Fusions are detected with the presence of 3 or more supporting reads passing pipeline filters and splice variants with 10 or more supporting reads. For fusions and splice variants, the overall sensitivity was 98.0% (151/154), specificity was 94.8% (91/96), and accuracy was 96.8% (242/250). Fusion and splice variant detection are most accurate at greater than or equal to 20% tumor purity.

Table. Analytical Sensitivity

Variant type	**Threshold for positivity**	**Recommended tumor purity**
SNV	> or =2% VAF with >150X median exon coverage	> or =20%
DELIN	> or =2% VAF, < or =20 bp	> or =20%
Gene amplification*	N/A	> or =40%
Homozygous gene deletion*	N/A	> or =40%
MSI status	> or =20% sites unstable= MSI-H	> or =40%
TMB status	> or =10 variants per megabase= TMB-High	> or =40%
Fusion	> or =3 supporting reads	> or =20%
Splice variant	> or =10 supporting reads	> or =20%

*Gene amplifications and homozygous deletions will be called by the bioinformatic pipeline and subjected to expert manual review to optimize sensitivity and specificity.

Performance

Method Description

Next-generation sequencing is performed to estimate tumor mutational burden and microsatellite instability status, somatic sequence variants, gene amplifications, homozygous gene deletions, gene fusions, and specific transcript variants in solid tumors. This test detects single nucleotide variants and small insertions and deletion within 515 genes, amplification of 96 genes, homozygous deletions in 133 genes, fusions involving 55 genes, and splice variants involving *EGFR*, *AR*, and *MET.*(Instruction manual: TruSight Oncology 500 High-Throughput. Illumina; 11/2020)

See Genes Interrogated by MayoComplete Solid Tumor Panel for details regarding genes interrogated by this test.

PDF Report
Supplemental

Day(s) Performed
Varies

Report Available
14 to 21 days

Specimen Retention Time
Tissue blocks: Unused portions of blocks will be returned; Tissue slides: Hematoxylin and eosin-stained and unstained slides will not be returned. Unused slides are stored for at least 5 years; Extracted DNA/RNA: 3 months

Performing Laboratory Location
Mayo Clinic Laboratories - Rochester Main Campus

Fees & Codes

Fees
- Authorized users can sign in to Test Prices for detailed fee information.
- Clients without access to Test Prices can contact Customer Service 24 hours a day, seven days a week.
- Prospective clients should contact their account representative. For assistance, contact Customer Service.

Test Classification
This test was developed and its performance characteristics determined by Mayo Clinic in a manner consistent with CLIA requirements. It has not been cleared or approved by the US Food and Drug Administration.
