Testing Algorithm

If hepatitis C virus (HCV) antibody is reactive, then HCV RNA detection and quantification by real-time reverse transcription-PCR will be performed at an additional charge.

If hepatitis B surface antigen is reactive, then confirmation will be performed at an additional charge.

The following algorithms are available in Special Instructions:

- Chronic Hepatitis C Treatment and Monitoring Algorithm: Direct Antiviral Antigen (DAA) Combination
- HBV Infection-Diagnostic Approach and Management Algorithm
- Hepatitis C: Testing Algorithm for Screening and Diagnosis
- Viral Hepatitis Serologic Profiles

Special Instructions

- Chronic Hepatitis C Treatment and Monitoring Algorithm: Direct Antiviral Agent (DAA) Combination
Method Name
Chemiluminescence Immunoassay (CIA)

NY State Available
Yes

Specimen

Specimen Type
Serum SST

Necessary Information
Date of draw is required.

Specimen Required
Collection Container/Tube: Serum gel
Submission Container/Tube: Plastic vial

Specimen Volume: 3 mL

Collection Instructions:
1. Centrifuge blood collection tube per collection tube manufacturer’s instructions.
2. Aliquot serum into plastic vial.

Forms
If not ordering electronically, complete, print, and send a Gastroenterology and Hepatology Client Test Request (T728) with the specimen.

Specimen Minimum Volume
2.75 mL

Clinical and Interpretive

Clinical Information

Hepatitis B:

Hepatitis B virus (HBV) is a DNA virus that is endemic throughout the world. The infection is spread primarily through percutaneous contact with infected blood products (e.g., blood transfusion, sharing of needles by drug addicts). The virus is also found in virtually every type of human body fluid and is known to be spread through oral and genital contact. HBV can be transmitted from mother to child during delivery through contact with blood and vaginal secretions; it is not commonly transmitted transplacentally.

After a course of acute illness, HBV persists in approximately 10% of patients. Some of these carriers are asymptomatic; others develop chronic liver disease including cirrhosis and hepatocellular carcinoma.

Hepatitis C:

Hepatitis C virus (HCV) is an RNA virus that is a significant cause of morbidity and mortality worldwide. HCV is transmitted through contaminated blood or blood products or through other close, personal contacts. It is recognized as the cause of most cases of post-transfusion hepatitis. HCV shows a high rate of progression (>50%) to chronic disease. In the United States, HCV infection is quite common, with an estimated 3.5 to 4 million chronic HCV carriers. Cirrhosis and hepatocellular carcinoma are sequelae of chronic HCV.

The following algorithms are available in Special Instructions:

- Chronic Hepatitis C Treatment and Monitoring Algorithm: Direct Antiviral Antigen (DAA) Combination
- HBV Infection-Diagnostic Approach and Management Algorithm
- Hepatitis C: Testing Algorithm for Screening and Diagnosis
- Viral Hepatitis Serologic Profiles

Unvaccinated: <5.0 mIU/mL

Vaccinated: > or =12.0 mIU/mL
HEPATITIS B CORE TOTAL ANTIBODIES

Negative

HEPATITIS C ANTIBODY

Negative

Interpretation depends on clinical setting.

**Interpretation**

Interpretation depends on clinical setting. See [Viral Hepatitis Serologic Profiles](#) in Special Instructions.

**Chronic Hepatitis B:**

Hepatitis B surface antigen (HBsAg) is the first serologic marker appearing in the serum 6 to 16 weeks following hepatitis B viral (HBV) infection. In acute cases, HBsAg usually disappears 1 to 2 months after the onset of symptoms. Persistence of HBsAg for more than 6 months indicates development of either a chronic carrier state or chronic HBV infection.

Hepatitis B core antibodies (anti-HBc Ab) appear shortly after the onset of symptoms of HBV infection and soon after the appearance of HBsAg. The IgM subclass usually falls to undetectable levels within 6 months, and the IgG subclass may remain for many years.

Hepatitis B surface antibody (anti-HBs) usually appears with the resolution of hepatitis B virus infection after the disappearance of HBsAg.

If HBsAg and anti-HBc (total antibody) are positive and patient's condition warrants, consider testing for hepatitis Be antigen (HBeAg), anti-HBe, hepatitis B virus DNA (HBV-DNA) or anti-hepatitis D virus (anti-HDV).

**Chronic Hepatitis C:**

Anti-HCV is almost always detectable by the late convalescent and chronic stage of infection.

The serologic tests currently available do not differentiate between acute and chronic hepatitis C infections.

**Cautions**

Positive hepatitis B surface antigen (HBsAg) test results should be reported by the attending physician to the State Department of Health as required by law in some states.

Consider administration of hepatitis B immune globulin (HBIG) and hepatitis B vaccine to HBsAg antibody negative individuals exposed to the HBsAg-positive patient's blood or body fluids.

Neonates (<1 month old) with positive hepatitis B core (anti-HBc) total antibody results from this assay method should be tested for anti-HBc IgM antibody to rule-out possible maternal anti-HBc total antibody causing false-positive results. Repeat testing for anti-HBc total antibody within 1 month is also recommended in these anti-HBc total antibody-positive neonates.

**Assay performance characteristics have not been established for:**

- Individuals under 10 years of age (HCVDX)
Test Definition: CRHEP
Chronic Hepatitis Profile

-Grossly icteric (total bilirubin level of >20 mg/dL)

-Grossly lipemic (triolein level of >3,000 mg/dL)

-Grossly hemolyzed (hemoglobin level of >500 mg/dL)

-Cadaveric specimens

-Those that contain particulate matter

Clinical Reference

Performance

Method Description

Hepatitis B Surface Antigen (HBsAg):

Specimens are first tested by the VITROS HBsAg assay. With modification to the assay manufacturer's instructions for use, specimens yielding signal-to-cutoff (S/CO) of 1.00 or greater but 100.0 or less will be confirmed by the VITROS HBsAg Confirmatory assay. Specimens that are strongly positive (ie, S/CO >100.0) do not require this confirmation. This immunometric technique involves the simultaneous reaction of HBsAg in the sample with mouse monoclonal hepatitis B surface antibody (anti-HBs) coated onto the wells and a horseradish peroxidase (HRP)-labeled mouse monoclonal anti-HBs antibody in the conjugate. Unbound conjugate is removed by washing. A reagent containing luminogenic substrates (a luminol derivative and a peracid salt) and an electron transfer agent is added to the wells. The HRP in the bound conjugate catalyzes the oxidation of the luminol derivative, producing light. The electron transfer agent increases the level and duration of the light produced. The light signals are read by the VITROS Immunodiagnostic System. The amount of HRP conjugate bound is indicative of the level of HBsAg present in the sample. (Package insert: VITROS HBsAg assay, no. GEM1201_US_EN, version 13.0; Ortho-Clinical Diagnostics, Inc. Rochester, NY 09-06-2019)

HBsAg Confirmation:

The VITROS HBsAg Confirmatory Kit uses the principle of specific antibody neutralization to confirm the presence of HBsAg. The sample is tested twice: 1 aliquot is incubated with a neutralizing reagent containing high titer anti-HBs (the confirmatory antibody); the second aliquot is incubated with a nonneutralizing control reagent (the sample diluent). The confirmatory antibody binds to HBsAg in the sample inhibiting its reaction in the VITROS HBsAg assay. This leads to a reduced result compared to that for the non-neutralized control sample. (Package insert: VITROS HBsAg Confirmatory Kit, no. GEM12011201_US_EN, version 13.0; Ortho-Clinical Diagnostics, Inc. Rochester, NY 09-06-2019)
HBsAg Confirmation assay, no. GEM4201_US_EN, version 13.1; Ortho-Clinical Diagnostics, Inc., Rochester, NY 10-05-2017

Hepatitis B Surface Antibody (anti-HBs):

VITROS anti-HBs quantitative assay is performed using the VITROS Anti-HBs Quantitative Reagent Pack and VITROS Immunodiagnostic Products Anti-HBs Calibrators on the automated VITROS Immunodiagnostic System.

This chemiluminescent immunoassay is based on an immunometric technique in which the anti-HBs present in the clinical serum sample reacts with HBsAg (ad and ay subtypes) coated onto the assay reaction wells. A horseradish peroxidase (HRP)-labeled HBsAg conjugate (ad and ay subtypes) then complexes with the bound anti-HBs forming an "antigen sandwich." Unbound materials are removed by washing.

A reagent containing luminogenic substrates (a luminol derivative and a peracid salt) and an electron transfer agent is added to the wells. HRP in the bound conjugate catalyzes the oxidation of the luminol derivative to produce light. The electron transfer agent increases the level and duration of the light produced. The light signals are detected by the VITROS Immunodiagnostic System. The amount of HRP conjugate bound is directly proportional to the concentration of anti-HBs antibody present. (Package insert: VITROS Anti-HBs Quantitative Assay, publication no. GEM1208_US_EN, v 13.1 Ortho-Clinical Diagnostics, Inc., Rochester, NY; 09-06-2019)

Hepatitis B Core Total Antibody:

The VITROS anti-hepatitis B core (anti-HBc) assay is a competitive immunoassay method based on the reaction of anti-HBc in the sample with hepatitis B core antigen (HBcAg)-coated wells. Unbound sample is removed by washing. HRP-labeled antibody conjugate (mouse monoclonal anti-HBc) is then allowed to react with the remaining exposed HBcAg on the well surface. Unbound conjugate is removed by washing.

The bound HRP conjugate is measured by a luminescent reaction. A reagent containing luminogenic substrates (a luminol derivative and a peracid salt) and an electron transfer agent is added to the wells. The HRP in the bound conjugate catalyzes the oxidation of the luminol derivative, producing light. The electron transfer agent increases the level and duration of the light produced. The light signals are read by the VITROS Immunodiagnostic System. The amount of HRP conjugate bound is indicative of the concentration of anti-HBc present in the sample. (Package insert: VITROS Anti-HBc Assay, no. GEM1211_US_EN, version 13.1; Ortho-Clinical Diagnostics, Inc. Rochester, NY 14626-5101 09-06-2019)

Hepatitis C Virus (HCV) Antibody:

The VITROS anti-HCV assay is performed using the VITROS Anti-HCV Reagent Pack and VITROS Immunodiagnostic Products Anti-HCV Calibrator on the automated VITROS Immunodiagnostic System. An immunometric technique is used, involving a 2-stage reaction. In the first stage, HCV antibody present in the sample binds to HCV recombinant antigens coated on the reaction wells, and unbound sample is removed by washing. In the second stage, HRP-labeled antibody conjugate (mouse monoclonal antihuman IgG) binds to human IgG captured on the well in the first stage. Unbound conjugate is removed by washing. A reagent containing luminogenic substrates (a luminol derivative and a peracid salt) and an electron transfer agent is added to the wells. The HRP in the bound conjugate catalyzes the oxidation of the luminol derivative, producing light. The electron transfer agent increases the level and duration of the light produced. The emitted light signals are detected and measured by the VITROS Immunodiagnostic System. The amount of HRP conjugate bound is directly proportional to the level of anti-HCV antibodies present in a given sample. (Package insert: VITROS Anti-HCV Assay, no. GEM1243_US_EN, version 14.0; Ortho-Clinical Diagnostics, Inc. Rochester, NY 14626-5101 10-03-2017)
