

## Overview

### Useful For

Ascertaining a pathogenic alteration in the *PROC* gene of patients with congenital protein C deficiency

This test is **not intended for** prenatal diagnosis

### Genetics Test Information

This test detects pathogenic alterations in the *PROC* gene to delineate the underlying molecular defect in a patient with a laboratory diagnosis of protein C deficiency.

The gene target for this test is:

Gene name (transcript): *PROC* (GRCh37 [hg19] NM\_000312)

Chromosomal location: 2q14.3

### Testing Algorithm

The clinical workup for protein C deficiency includes special coagulation testing for protein C activity (CFX / Protein C Activity, Plasma).

Genetic testing for protein C deficiency is indicated if:

-Protein C activity is reduced (<75% of normal)

-Acquired causes of protein C deficiency have been excluded (eg, vitamin K deficiency, oral anticoagulation with coumarin compounds, liver disease, intravascular coagulation and fibrinolysis/disseminated intravascular coagulation: ICF/DIC)

If protein C activity is low, protein C antigen testing (PCAG / Protein C Antigen, Plasma) helps to distinguish between type I and type II deficiencies.

### Special Instructions

- [Informed Consent for Genetic Testing](#)
- [Informed Consent for Genetic Testing \(Spanish\)](#)
- [Rare Coagulation Disorder Patient Information](#)

### Method Name

Custom Sequence Capture and Targeted Next-Generation Sequencing (NGS) followed by Polymerase Chain Reaction (PCR) and Sanger sequencing when appropriate

### NY State Available

Yes

## Specimen

### Specimen Type

Varies

**Advisory Information**

Genetic testing should only be performed if protein C activity is abnormally reduced and acquired causes of protein C deficiency have been excluded.

**Shipping Instructions**

1. Ambient and refrigerated specimens must arrive within 7 days, and frozen specimens must arrive within 14 days of collection
2. Collect and package specimen as close to shipping time as possible.

**Necessary Information**

[Rare Coagulation Disorder Patient Information](#) is required, see Special Instructions. Testing may proceed without the patient information, however, the information aids in providing a more thorough interpretation. Ordering providers are strongly encouraged to fill out the form and send with the specimen.

**Specimen Required**

**Submit only 1 of the following specimens:**

**Specimen Type:** Peripheral blood

**Container/Tube:**

**Preferred:** Lavender top (EDTA)

**Acceptable:** Yellow top (ACD) or green top (sodium citrate)

**Specimen Volume:** 3 mL

**Collection Instructions:**

1. Invert several times to mix blood.
2. Send specimen in original tube.

**Specimen Stability:** Ambient (preferred)/Refrigerate/Frozen

**Specimen Type:** Extracted DNA

**Container/Tube:** 1.5- to 2-mL tube

**Specimen Volume:** Entire specimen

**Collection Instructions:**

1. Label specimen as extracted DNA and source of specimen.
2. Provide volume and concentration of the DNA.

**Specimen Stability:** Frozen (preferred)/Refrigerate/Ambient

**Forms**

1. [Rare Coagulation Disorder Patient Information \(T824\)](#) is required, see Special Instructions. Fax the completed form to 507-284-1759.

2. **New York Clients-Informed consent is required.** Document on the request form or electronic order that a copy is on file. The following documents are available in Special Instructions:

-[Informed Consent for Genetic Testing \(T576\)](#)

-[Informed Consent for Genetic Testing-Spanish \(T826\)](#)

3. If not ordering electronically, complete, print, and send a [Coagulation Test Request \(T753\)](#) with the specimen.

### Specimen Minimum Volume

Blood: 1 mL blood

Extracted DNA: 100 mcL at 50 ng/mcL concentration

### Reject Due To

Gross hemolysis	OK
Gross lipemia	OK

### Specimen Stability Information

Specimen Type	Temperature	Time	Special Container
Varies	Ambient (preferred)	7 days	
	Frozen	14 days	
	Refrigerated	7 days	

## Clinical and Interpretive

### Clinical Information

Protein C is a vitamin K-dependent plasma glycoprotein synthesized in the liver. After secretion, protein C circulates in blood mostly in its inactive form until cleaved at residues Arg211-Leu212 to form activated protein C. Activated protein C and its cofactor, protein S, act as a potent anticoagulant by cleaving and inactivating procoagulant factors VIIIa and Va. A deficiency of protein C results in impairment of the ability to control coagulation through the inactivation of procoagulant factors, factor Va and factor VIIIa, leading to an increased risk of venous thrombosis. While protein C deficient individuals are 7 to 10 times more likely to develop venous thromboembolism (VTE), 3% to 9% of these individuals actually develop a VTE, and the annual risk of VTE is between 0.4% and 1.0% per year.(1)

Congenital protein C deficiency is classified into two types. Type I deficiency is characterized by decreased protein synthesis or increased intracellular protein degradation that lead to lower levels of protein C in blood. Type I deficiency accounts for about 75% of all cases of congenital protein C deficiency. Type II deficiency is characterized by dysfunctional protein C that is produced in normal amounts. There appears to be no clinical differences between type I and type II phenotypes. Protein C antigen testing (PCAG / Protein C Antigen, Plasma) is helpful to distinguish between type I and type II deficiencies and in cases where genetic testing results yield variants of uncertain significance (VUS).

---

The *PROC* gene encodes for protein C. Pathogenic alterations in the gene can cause congenital protein C deficiency. Congenital protein C deficiency is inherited as an autosomal dominant disorder but with variable penetrance. Both men and women can be affected. The estimated prevalence of protein C deficiency ranges from 200 to 400 per 100,000. Individuals who are heterozygous for a pathogenic *PROC* alteration are at increased risk for VTE and warfarin-induced skin necrosis. The co-inheritance of additional thrombotic risk factors, eg, factor V Leiden, can compound this risk, leading to a clinically significant disorder. Homozygosity or compound heterozygosity for pathogenic alterations in the *PROC* gene is associated with severe protein C deficiency, which presents in infancy as the development of cerebral vein thrombosis or neonatal pupura fulminans (ie, widespread cutaneous hemorrhage and tissue death due to thrombosis of the microvascular.) These infants typically have protein C levels that virtually undetectable. Severe protein C deficient patients with very low but detectable protein C levels typically present with thromboembolic disease during early childhood or adulthood.(2)

Causes of acquired (non-genetic) protein C deficiency that should be excluded prior to genetic testing include vitamin K deficiency, oral anticoagulation with coumarin compounds, liver disease, and intravascular coagulation and fibrinolysis/disseminated intravascular coagulation (ICF/DIC).

### Reference Values

An interpretive report will be provided.

### Interpretation

An interpretive report will be provided. Evaluation and categorization of variants is performed using the most recent published American College of Medical Genetics and Genomics (ACMG) recommendations as a guideline. Variants are classified based on known, predicted, or possible pathogenicity and reported with interpretive comments detailing their potential or known significance.

Consultations with the Mayo Clinic Special Coagulation Clinic, Molecular Hematopathology Laboratory, and Thrombophilia Center are available for DNA diagnosis cases. This may be especially helpful in complex cases or in situations where the diagnosis is atypical or uncertain.

### Cautions

Clinical:

Some individuals may have a mutation that is not identified by the methods performed. The absence of a mutation, therefore, does not eliminate the possibility of protein C deficiency. This assay does not distinguish between germline and somatic alterations, particularly with variant allele frequencies (VAF) significantly lower than 50%. Test results should be interpreted in context of clinical findings, family history, and other laboratory data. Misinterpretation of results may occur if the information provided is inaccurate or incomplete.

If there is a family history of protein C deficiency, it is often useful to test first-degree family members to help establish the clinical significance of variants of unknown significance.

Technical Limitations:

Next-generation sequencing (NGS) may not detect all types of genetic variants. Additionally, rare polymorphisms may be present that could lead to false-negative or false-positive results. Therefore test results should be interpreted in the context of activity and antigen measurements, clinical findings, family history, and other laboratory data. If results do not match clinical findings, consider alternative methods for analyzing these genes, such as Sanger sequencing or large deletion/duplication analysis. Misinterpretation of results may occur if the information provided is inaccurate or incomplete.

If multiple alterations are identified, NGS is not able to distinguish between alterations that are found in the same allele ("in cis") and alterations found on different alleles ("in trans"). This limitation may complicate diagnosis or

classification and has implications for inheritance and genetic counseling. To resolve these cases, molecular results must be correlated with clinical history, activity and antigen measurements, and/or family studies.

Unless reported or predicted to cause disease, alterations found deep in the intron or alterations that do not result in an amino acid substitution are not reported. These and common polymorphisms identified for this patient are available upon request.

#### Reclassification of Variants Policy:

At this time, it is not standard practice for the laboratory to systematically review likely pathogenic variants or variants of uncertain significance that are detected and reported. The laboratory encourages health care providers to contact the laboratory at any time to learn how the status of a particular variant may have changed over time.

### Performance

#### Method Description

Next-generation sequencing (NGS) and/or Sanger sequencing are performed.

Regions of homology, high guanine-cytosine (GC)-rich content, and repetitive sequences may not provide accurate sequence. Therefore, all reported alterations detected by NGS in these regions are confirmed by an independent reference method. However, this does not rule out the possibility of a false-negative result in these regions.

Sanger sequencing is used to confirm alterations detected by NGS when appropriate. (Unpublished Mayo method)

#### PDF Report

No

#### Day(s) and Time(s) Test Performed

Performed weekly, Varies

#### Analytic Time

21 days

**Maximum Laboratory Time**

28 days

**Specimen Retention Time**

Whole Blood: 2 weeks; DNA: Indefinitely
