Overview

Useful For
Detection of antibodies to *Echinococcus* species, including *E. multilocularis* and *E. granulosus*.

Method Name
Enzyme Immunoassay (EIA)

NY State Available
Yes

Specimen

Specimen Type
Serum

Specimen Required
Container/Tube:
Preferred: Serum gel
Acceptable: Red top

Specimen Volume: 0.5 mL

Forms
If not ordering electronically, complete, print, and send a Microbiology Test Request (T244) with the specimen.

Specimen Minimum Volume
0.2 mL

Reject Due To

| Gross hemolysis | Reject |
| Gross lipemia  | Reject |

Clinical and Interpretive

Clinical Information
Echinococcosis, also referred to as hydatidosis or hydatid disease, is 1 of the 17 neglected tropical diseases recognized by the World Health Organization, and affects over 1 million people worldwide. *Echinococcus* species are tapeworms or cestodes and 2 main species infect humans: *E granulosus* and *E multilocularis*.

With respect to geographic distribution, *E granulosus* can be found worldwide, but more frequently in rural grazing areas where dogs may feed on infected sheep or cattle carcasses. *E multilocularis* is largely localized to the northern hemisphere. The definitive hosts for *E granulosus* are dogs or other canids, while the definitive host for *E multilocularis* are foxes and, to a much lesser extent, canids. *Echinococcus* tapeworms reside in the small intestine of definitive hosts and release eggs that are passed in the feces and ingested by an intermediate host, typically sheep or cattle in the case of *E granulosus* or small rodents for *E multilocularis*. The eggs hatch in the small bowel, releasing an oncosphere, which penetrates the intestinal wall and migrates through the circulatory system to various organs where it will develop into a cyst that gradually enlarges producing protoscolicies and daughter cysts that fill the interior. The definitive host becomes infected following ingestion of these infectious cysts. Humans become accidentally infected following ingestion of *Echinococcus* eggs.

In humans, *E granulosus* (cystic echinococcal disease) cysts typically develop in the lungs and liver and the infection may remain silent or latent for years (5-20 years) prior to cyst enlargement and symptom manifestation. Symptomatic manifestations include chest pain, hemoptysis and cough for pulmonary involvement and abdominal pain and biliary duct obstruction for liver infection. *E multilocularis* (alveolar echinococcal disease) infections manifest more rapidly than those of *E granulosus*, and manifests similar to a rapidly growing, destructive tumor resulting in abdominal pain and biliary obstruction. Rupture of cysts can produce fever, urticaria, and anaphylactic shock.

Diagnosis of echinococcal infections relies on characteristic finding by ultrasound or other imaging techniques and serologic findings. Fine-needle aspirates of cystic fluid may be performed; however, they carry the risk of cyst puncture and fluid leakage, which may potentially lead to severe allergic reactions. Importantly, infected individuals do not shed eggs in stool.

**Reference Values**

Negative

Reference values apply to all ages.

**Interpretation**

Negative: the absence of antibodies to *Echinococcus* species suggests that the individual has not been exposed to this cestode. A single negative result should not be used to rule-out infection (see Cautions).

Equivocal: consider repeat testing on a new serum sample in 1 to 2 weeks.

Positive: results suggest infection with *Echinococcus*. False-positive results may occur in settings of infection with other helminths, or in patients with chronic immune disorders. Results should be considered alongside other clinical findings (eg, characteristic findings on imaging) and exposure history.

**Cautions**

Depending on cyst location, individuals may not develop high enough antibody titers to be detectable by serologic assays, leading to false-negative results. Cysts localized to the lungs, central nervous system or spleen, or cysts that are senescent, calcified, or dead are associated with lower serologic reactivity.

False-positive results may occur in patients with other helminth infections, including with *Taenia* species, *Schistosoma* species, and *Strongyloides*. Careful correlation with imaging findings and exposure history is required.

This assay may not detect antibodies to other species of *Echinococcus*, including *E vogeli* and *E oligarthrus*, both fairly uncommon causes of hydatid disease in humans.
Supportive Data

The Mayo Infectious Disease Serology laboratory evaluated the accuracy of the RidaScreen *Echinococcus* IgG ELISA (as performed in our laboratory) using 58 serum samples previously tested by the serologic assays offered at Focus Diagnostics. A comparison of the result is shown in Table 1.

Positive Agreement (95% CI): 90.5% (69.9-98.6)

Negative Agreement (95% CI): 86.5% (71.6-94.6)

Overall Agreement (95% CI): 87.9% (76.8-94.3)

The Mayo Infectious Disease Serology laboratory also evaluated the analytic specificity of the RidaScreen *Echinococcus* IgG ELISA by testing 36 serum samples positive for antibodies to other helminth and protozoa. The results are shown in Table 2.

The reference range for the RidaScreen *Echinococcus* IgG ELISA was evaluated by testing serum from 50 normal donors; 49/50 (98%) of healthy individuals were negative by this ELISA.

Clinical Reference
Performance

Method Description

Purified antigens are bonded to a microwell plate. Antibodies that are present in the patient samples attach themselves to the antigens and are determined during the second phase of the test by using enzyme-labelled antihuman antibodies (the conjugate). The enzyme converts the colorless substrate (urea peroxide/TMP) to a blue endproduct. The enzyme reaction is stopped by adding sulphuric acid. The colour of the mixture then switches from blue to yellow. A final measurement is carried out in a photometer at 450 nm using a reference wavelength of > or =620 nm. (Package insert: RIDASCREEN Echinococcus IgG, R-Biopharm AG, Darmstadt, Germany, 9/2015)

Fees and Codes

Fees

- Authorized users can sign in to Test Prices for detailed fee information.
- Clients without access to Test Prices can contact Customer Service 24 hours a day, seven days a week.
- Prospective clients should contact their Regional Manager. For assistance, contact Customer Service.

Test Classification

This test has been modified from the manufacturer's instructions. Its performance characteristics were determined by Mayo Clinic in a manner consistent with CLIA requirements. This test has not been cleared or approved by the U.S. Food and Drug Administration.
