

Histoplasma and Blastomyces Antigen, Enzyme Immunoassay, Urine

## Overview

## **Useful For**

Diagnosing *Histoplasma capsulatum* or *Blastomyces dermatitidis* infection, without differentiation between the organisms, using random urine specimens

Monitor antigen levels following initiation of antifungal treatment

# **Highlights**

This test detects *Histoplasma* and *Blastomyces* antigen in urine, without differentiation between the 2 fungal pathogens.

This test aids in the diagnosis of histoplasmosis or blastomycosis alongside other routine methods, including culture, molecular testing, and serology.

This test can be used to monitor response to antifungal therapy.

### **Method Name**

Enzyme Immunoassay (EIA)

## **NY State Available**

Yes

# **Specimen**

# **Specimen Type**

Urine

# Specimen Required

Supplies: Sarstedt Aliquot tube, 5 mL (T914)

Container/Tube: Plastic vial Specimen Volume: 3 mL Collection Instructions:

- 1. Collect a random urine specimen, with no preservative.
- 2. Do not centrifuge to remove particulates.

## **Forms**

If not ordering electronically, complete, print, and send 1 of the following forms with the specimen:

- -Kidney Transplant Test Request
- -Infectious Disease Serology Test Request (T916)

Histoplasma and Blastomyces Antigen, Enzyme Immunoassay, Urine

Specimen	Minimum	Volume
----------	---------	--------

2.5 mL

# **Reject Due To**

Gross	Reject
hemolysis	
Turbid	Reject
Colored	

# **Specimen Stability Information**

Specimen Type	Temperature	Time	Special Container
Urine	Refrigerated (preferred)	14 days	
	Ambient	7 days	
	Frozen	28 days	

# **Clinical & Interpretive**

#### Clinical Information

Blastomyces dermatitidis and Histoplasma capsulatum are dimorphic fungal agents with increasingly overlapping endemicity throughout the Midwestern, South Central, and Southeastern United States, particularly in regions around the Ohio and Mississippi River valleys, the Great Lakes, and the Saint Lawrence River. These agents are also found in regions of Canada.

These 2 fungi maintain a yeast form in the host at body temperature but are maintained as molds in the environment, which release spores that are inhaled by individuals leading to infection. Through phylogenetic analysis, *B dermatitidis* has been separated into 2 distinct species: *B dermatitidis* and *Blastomyces gilchristii*, both able to cause blastomycosis. *B dermatitidis* infections are frequently associated with dissemination, particularly in older patients, smokers, and immunocompromised hosts, while *B gilchristii* has primarily been associated with pulmonary and constitutional symptoms. Additional species of *Blastomyces* have recently been discovered and characterized; however, the performance characteristics of this assay for these species are unknown.

Approximately half of patients infected with *Blastomyces* will develop symptoms that are frequently nonspecific, including fever, cough, night sweats, myalgia or arthralgia, weight loss, dyspnea, chest pain, and fatigue. Symptoms may appear anywhere from 3 weeks to 3 months following infection.

For *Histoplasma* infections, clinical manifestations are largely dependent on the fungal burden at the time of exposure and the patient's underlying immune status. While the vast majority (>90%) of exposed individuals will remain asymptomatic, individuals seeking medical attention can present with a diverse set of symptoms ranging from a self-limited pulmonary illness to severe, disseminated disease. Individuals at risk of severe infection include those with impaired cellular immunity or have undergone organ transplantation, are HIV positive, or have a hematologic malignancy.

Histoplasma and Blastomyces Antigen, Enzyme Immunoassay, Urine

Diagnosis of blastomycosis and histoplasmosis relies on a combination of assays, including culture and molecular testing performed on appropriate specimens, and serologic evaluation for both antibodies to, and antigen released from, the organism. Although culture remains the gold standard method and is highly specific, these organisms can take several days to weeks to grow, and sensitivity is diminished in cases of acute or localized disease. Similarly, molecular testing offers high specificity and a rapid turnaround time, however sensitivity is imperfect. Detection of an antibody response to *Blastomyces* or *Histoplasma* offers high specificity; however, results may be falsely negative in patients who are acutely ill or are immunosuppressed.

#### **Reference Values**

Histoplasma/Blastomyces Antigen Result:

Not detected

Histoplasma/Blastomyces Antigen Value:

Not detected: 0.0 ng/mL Detected: <1.3 ng/mL Detected: 1.3-20.0 ng/mL Detected: >20.0 ng/mL

Reference values apply to all ages.

## Interpretation

Not detected:

No antigen from *Histoplasma* or *Blastomyces* detected. False-negative results may occur depending on the extent of disease or site of infection. Repeat testing on a new specimen if clinically indicated.

#### Detected:

Antigen from *Histoplasma* or *Blastomyces* (unable to differentiate) was detected, below the limit of quantification (<1.3 ng/mL). Definitive identification requires additional testing, including serology, culture, histopathology, and/or molecular methods. Results should be correlated with clinical presentation and exposure history.

#### Detected:

Antigen from *Histoplasma* or *Blastomyces* (unable to differentiate) detected. Definitive identification requires additional testing, including serology, culture, histopathology, and/or molecular methods. Results should be correlated with clinical presentation and exposure history.

#### Detected:

Antigen from *Histoplasma* or *Blastomyces* (unable to differentiate) detected, above the limit of quantification (>20.0 ng/mL). Definitive identification requires additional testing, including serology, culture, histopathology, and/or molecular methods. Results should be correlated with clinical presentation and exposure history.

## **Cautions**

Due to significant cross-reactivity between galactomannan antigens from *Blastomyces* and *Histoplasma*, this assay does not differentiate between these 2 dimorphic fungal agents. To differentiate, consider fungal culture, molecular testing, or serology testing.

Histoplasma and Blastomyces Antigen, Enzyme Immunoassay, Urine

Positive results should be correlated with other clinical and laboratory findings (eg, culture, serology).

Low-level positive antigen levels may persist following resolution of infection and completion of appropriate treatment regimen.

Sensitivity of this assay to detect antigens from species other than *Blastomyces dermatitidis* or *Histoplasma capsulatum* is unknown.

False-positive results may occur less frequently with other dimorphic agents (eg, Coccidioides).

## **Performance**

## **Method Description**

The assay detects *Blastomyces dermatitidis* antigen in human serum samples using specific, proprietary antibodies in an enzyme-linked immunosorbent assay format. The detection method involves an enzyme/substrate system with the level of urinary *B dermatitidis* antigen proportional to the assay signal. The patient specimen result is compared to a cutoff calibrator and a standard curve of a series of assay calibrators (1.25 to 20.00 ng/mL) to determine the presence or absence of antigen and, if present, to establish a quantitative level of *B dermatitidis* serum antigen.(Package insert: *Blastomyces dermatitidis* Urinary Antigen Detection Kit.
