

Overview

Useful For

Confirming the presence of listed synthetic glucocorticoids in serum specimens (see Interpretation)

Confirming the cause of glucocorticoid-induced adrenal insufficiency

This test is **not useful** for detection of fluticasone propionate.

Method Name

Liquid Chromatography Tandem Mass Spectrometry (LC-MS/MS)

NY State Available

Yes

Specimen

Specimen Type

Serum

Specimen Required

Supplies: Sarstedt Aliquot Tube, 5 mL (T914)

Collection Container/Tube:

Preferred: Red top

Acceptable: Serum gel

Submission Container/Tube: Plastic vial

Specimen Volume: 2 mL Serum

Collection Instructions: Centrifuge and aliquot serum into a plastic vial.

Specimen Minimum Volume

Serum: 1.1 mL

Reject Due To

Gross hemolysis	OK
Gross lipemia	OK
Gross icterus	OK

Specimen Stability Information

Specimen Type	Temperature	Time	Special Container
Serum	Frozen (preferred)	14 days	
	Ambient	24 hours	
	Refrigerated	7 days	

Clinical & Interpretive

Clinical Information

The primary use of this test is to assess exposure to synthetic glucocorticoids in patients with suspected central adrenal insufficiency.

Synthetic glucocorticoids are widely used as anti-inflammatory and immunosuppressive agents. Synthetic glucocorticoids can be used through various routes: oral, intravenous, intramuscular, inhaled, intranasal, and topical. In most cases, exposure to synthetic glucocorticoids is clearly documented in the medical record. However, occasionally, exposure to synthetic glucocorticoids is not clearly evident. This may occur when patients use non-prescription preparations (usually oral or topical) that have glucocorticoids.

Exposure to synthetic glucocorticoids leads to development of features of Cushing syndrome (weight gain, abdominal obesity, moon facies, skin thinning, easy bruising, and metabolic comorbidities) or to glucocorticoid-induced adrenal insufficiency due to hypothalamic-pituitary-adrenal axis suppression by the circulating supraphysiologic synthetic glucocorticoids. Hormonal work up in these cases demonstrates very low corticotropin and cortisol concentrations.

This test allows for measurement of nine synthetic glucocorticoids in patients in whom exogenous glucocorticoid exposure is suspected.

Reference Values

Negative

Cutoff concentrations

Betamethasone: 0.10 mcg/dL

Budesonide: 0.20 mcg/dL

Dexamethasone: 0.10 mcg/dL

Fludrocortisone: 0.10 mcg/dL

Megestrol acetate: 0.10 mcg/dL

Methylprednisolone: 0.10 mcg/dL

Prednisolone: 0.10 mcg/dL

Prednisone: 0.10 mcg/dL

Triamcinolone acetonide: 0.10 mcg/dL

Values for normal patients not taking these synthetic glucocorticoids should be less than the cutoff concentration (detection limit).

Interpretation

This test screens for and quantitates, if present, the following synthetic glucocorticoids: betamethasone, budesonide, dexamethasone, fludrocortisone, megestrol acetate, methylprednisolone, prednisolone, prednisone, and triamcinolone

acetone.

The presence of synthetic glucocorticoids in serum indicates current or recent use of these compounds. Since several of these compounds exceed the potency of endogenous cortisol by 1 or more orders of magnitude, even trace levels may cause hypothalamic-pituitary-adrenal axis suppression with development of glucocorticoid-induced adrenal insufficiency.

Cautions

This method cannot detect all available synthetic steroids available either as pharmaceutical compounds or chemicals present in food. The assay confirms only the listed synthetic glucocorticoids. For more information see Interpretation.

Lack of detection of listed synthetic glucocorticoids does not exclude previous exposure to one or more of tested glucocorticoids, as glucocorticoid-induced adrenal insufficiency (and resolution of features of overt Cushing syndrome) may persist for weeks-months after exogenous glucocorticoids were discontinued. In a patient with documented glucocorticoid exposure, circulating concentrations of synthetic glucocorticoids depend on the route of administration (detected for longer time if joint injection), dose and type of glucocorticoid that influence metabolism and clearance of the glucocorticoid (longer for triamcinolone).

Performance

Method Description

The synthetic glucocorticoids (betamethasone, budesonide, dexamethasone, fludrocortisone, megestrol acetate, methylprednisolone, prednisolone, prednisone, triamcinolone acetone) as well as cortisol and cortisone are extracted

from 0.5 mL of urine or serum using an acetonitrile protein precipitation followed by liquid/liquid extraction of the supernatant. Cortisol-d4, triamcinolone-d1 acetonide-d6, dexamethasone-d4, and cortisone-d7, are added to each sample before the acetonitrile protein precipitation and serve as the internal standards. The reconstituted sample extract is injected onto a high performance liquid chromatography system and analyzed by liquid chromatography tandem mass spectrometry.(Taylor RL, Grebe SK, Singh RJ. Quantitative, highly sensitive liquid chromatography-tandem mass spectrometry method for detection of synthetic corticosteroids. Clin Chem. 2004;50[12]:2345-52. doi:10.1373/clinchem.2004.033605)
