

## Overview

### Useful For

Indicating chronic alcohol abuse

This test is **not appropriate** for screening patients for congenital disorders of glycosylation.

### Highlights

Patients with chronic alcoholism demonstrate increased levels of carbohydrate deficient transferrin over the amount of normally glycosylated tetrasialotransferrin.

### Method Name

Affinity Chromatography/Mass Spectrometry (MS)

### NY State Available

Yes

## Specimen

### Specimen Type

Serum

### Ordering Guidance

This test is for evaluation of alcohol abuse. If the ordering healthcare professional is looking for congenital disorders of glycosylation, order CDG / Carbohydrate Deficient Transferrin for Congenital Disorders of Glycosylation, Serum.

### Necessary Information

1. Patient's age is required.
2. Reason for testing is required if patient is younger than 21 years.

### Specimen Required

**Supplies:** Sarstedt Aliquot Tube, 5 mL (T914)

**Collection Container/Tube:**

**Preferred:** Serum gel

**Acceptable:** Red top

**Submission Container/Tube:** Plastic vial

**Specimen Volume:** 0.1 mL Serum

**Collection Instructions:** Centrifuge and aliquot serum into a plastic vial.

### Forms

If not ordering electronically, complete, print, and send a [Therapeutics Test Request](#) (T831) with the specimen.

**Specimen Minimum Volume**

Serum: 0.05 mL

**Reject Due To**

Gross hemolysis	OK
Gross lipemia	OK
Gross icterus	OK

**Specimen Stability Information**

Specimen Type	Temperature	Time	Special Container
Serum	Frozen (preferred)	45 days	
	Ambient	7 days	
	Refrigerated	28 days	

**Clinical & Interpretive****Clinical Information**

Chronic alcoholism causes a transient change in the glycosylation pattern of transferrin where the relative amounts of disialo- and asialotransferrin (carbohydrate deficient transferrin: CDT) are increased over the amount of normally glycosylated tetrasialotransferrin. This recognition led to the use of CDT in serum as a marker for chronic alcohol abuse.

Carbohydrate deficient transferrin typically normalizes within several weeks of abstinence of alcohol use. However, it is important to recognize that there are other causes of abnormal CDT levels, which include congenital disorders of glycosylation and other genetic and nongenetic causes of acute or chronic liver disease.

Carbohydrate deficient transferrin testing alone is not recommended for general screening for alcoholism; however, when combined with other methods (ie, gamma-glutamyltransferase, mean corpuscular volume, patient self-reporting, ethylglucuronide analysis), clinicians can expect to identify the majority of patients who consume a large amount of alcohol.

**Reference Values**

&lt; or =0.10

0.11-0.12 (Indeterminate)

**Interpretation**

Patients with chronic alcoholism may develop abnormally glycosylated transferrin isoforms (ie, carbohydrate deficient transferrin: CDT >0.12). CDT results from 0.11 to 0.12 are considered indeterminate.

Patients with liver disease due to genetic or nongenetic causes may also have abnormal results.

---

**Cautions**

This assay has not been fully validated for the investigation of alcoholism.

Carbohydrate deficient transferrin (CDT) testing alone is not recommended for general screening for alcoholism. Analysis of more than one biomarker is recommended to avoid misinterpretation of results.

The abnormal transferrin isoform pattern in patients with chronic alcoholism is similar to that observed in congenital disorders of glycosylation (CDG). However, unlike most patients with CDG, the relative amount of monoglycosylated transferrin is much lower. Other conditions such as hereditary fructose intolerance, galactosemia, and liver disease may result in increased levels of CDT. In addition, preanalytic variables such as bacterial contamination may cause falsely elevated CDT values. Several factors may cause variability in CDT analysis, including ethnicity, sex, pregnancy, body mass index, smoking, blood pressure, iron metabolism, drug interactions, and chronic medical illness.
